

Descartes-Origins: A Simulation-Based Approach to Costs and Schedules of Future Spaceplace Development Programs

Space 2010 Conference & Exposition

American Institute of Aeronautics and Astronautics
Anaheim Convention Center, Pasadena, CA
2 September 2010

Mr. Michael J. Kelly

Operations Engineer, Engineering Economics Group
SpaceWorks Engineering, Inc.
michael.kelly@sei.aero

Dr. Ronald P. Menich

Space Scenario Analyst, Engineering Economics Group
SpaceWorks Engineering, Inc.
ron.menich@sei.aero

Dr. John R. Olds

Principal Engineer
SpaceWorks Engineering, Inc.
john.olds@sei.aero

- ▶ History of predicting costs for Reusable Launch Vehicles shows room for improvement
- ▶ Theoretical cost advantage of RLVs lies in the elimination of additional production while adding recurring ground operations costs
- ▶ To effectively compare RLV to ELV solutions, a full Life Cycle Cost estimate is needed, including:
 - DDT&E (design, development, test and evaluation)
 - TFU (theoretical first unit production)
 - Facilities, additional production, and any other non-recurring costs
 - Maintenance, ground operations, and other recurring costs

STS turnaround projected to be 2 weeks

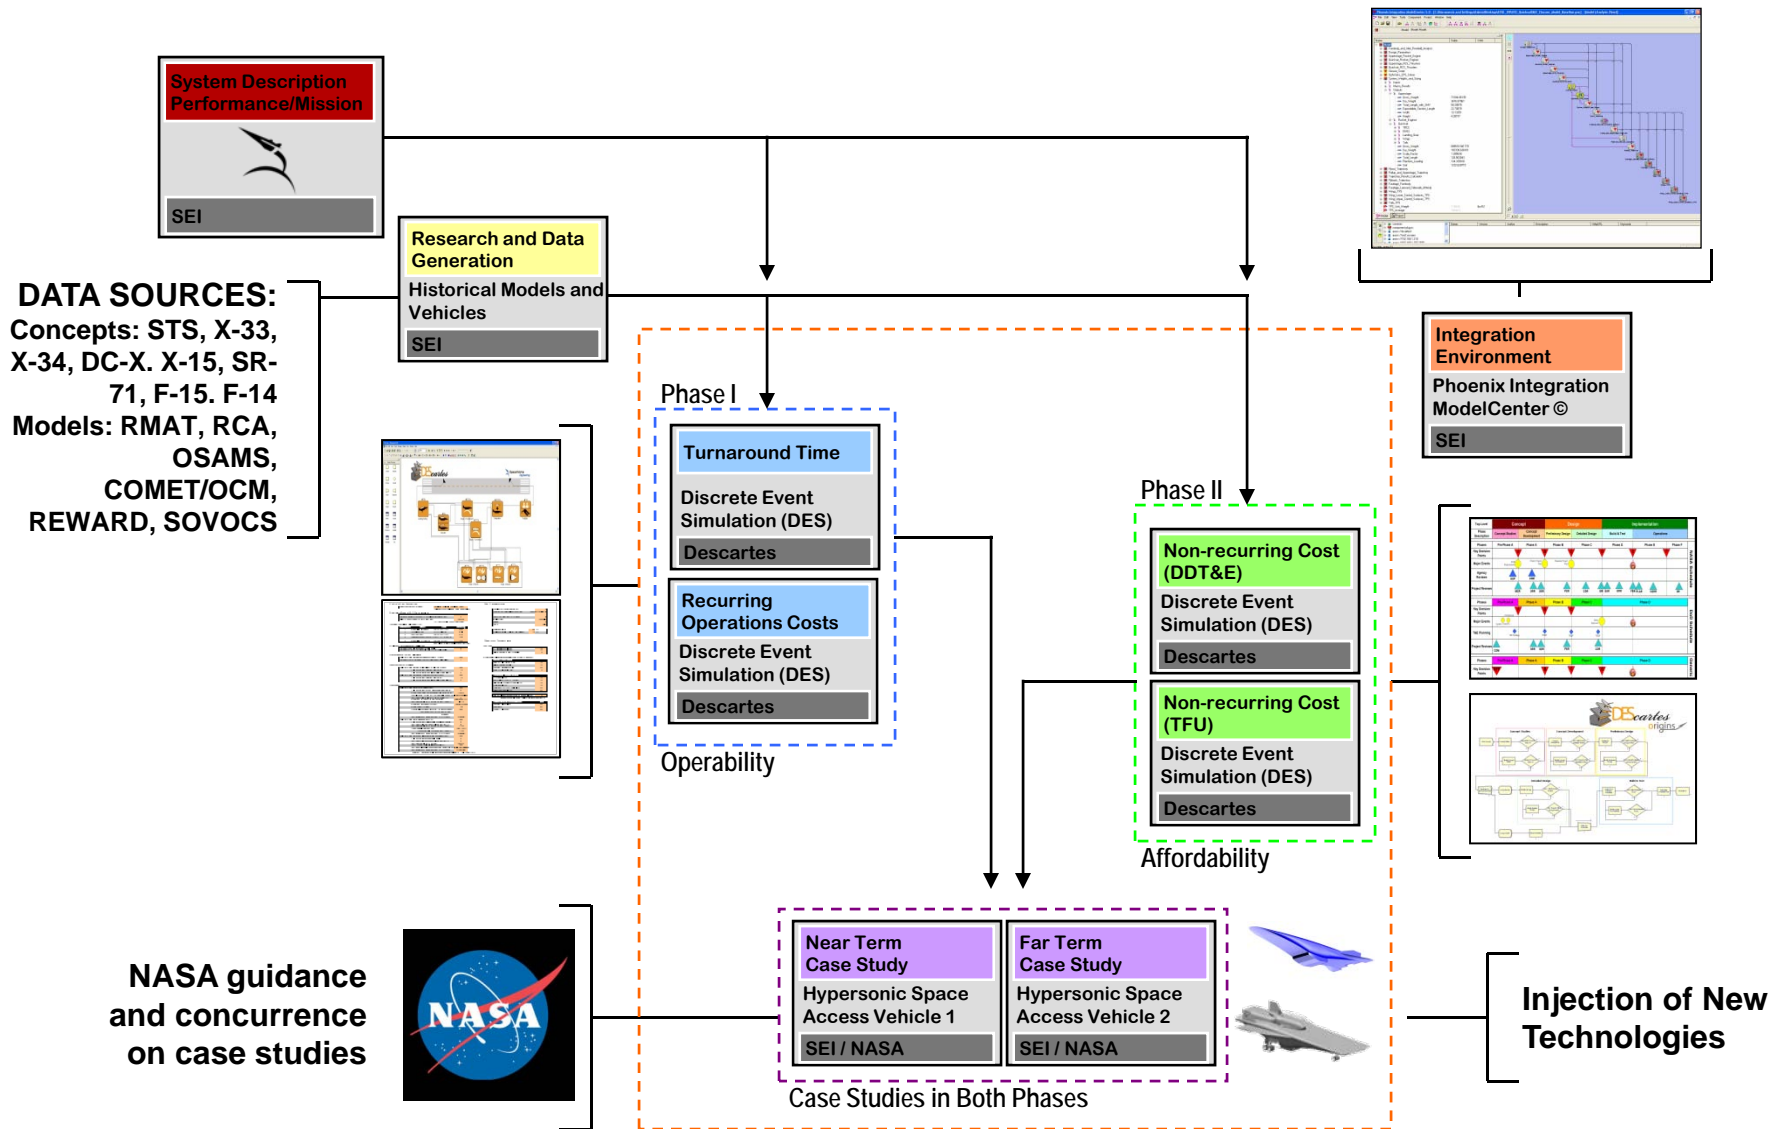

Actual turnaround takes over 3 months

Life Cycle Economics Analysis

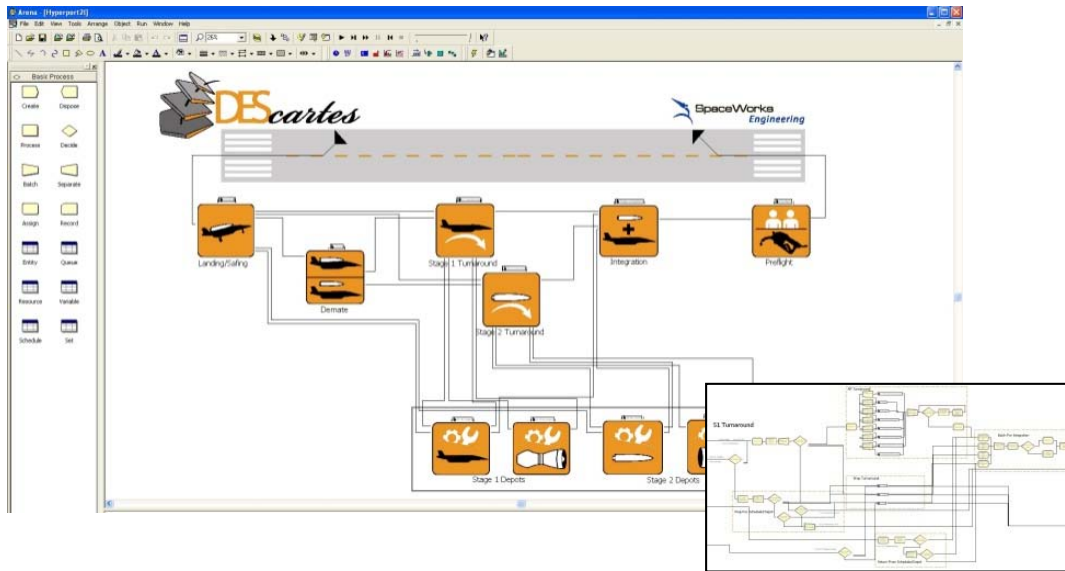

- ▶ In Discrete Event Simulation (DES), the operation of a system is represented as a chronological sequence of events
 - DES models use entities, resources, and various flow-chart-like processing blocks to represent complex systems
 - DES models can account for interaction of resources, complicated logical flows, and track numerous processes occurring in parallel and/or in series
- ▶ Rockwell Automation's Arena is among the industry-leading DES software packages
 - Arena provides graphical user interface and ability to animate entity flows over a base of the SIMAN DES language
 - Complex modeling possible with just create, dispose, process, decide, batch, separate, assign, and record blocks, along with entities, resources, variables, and Visual Basic manipulation
 - SEI uses Arena Basic Edition version 13.5 for DES modeling

- ▶ Each orange block contains processes modeling a major portion of the turnaround process, such as activity at a single facility
- ▶ Model takes over 100 vehicle inputs, along with labor and facility availabilities
- ▶ Outputs include:
 - Turnaround times broken down by stage and subsystem
 - Recurring costs including labor, fuel, spares, and periodic depot visits

Hyperport Model (see AIAA 2009-6484, AIAA 2010-2326)

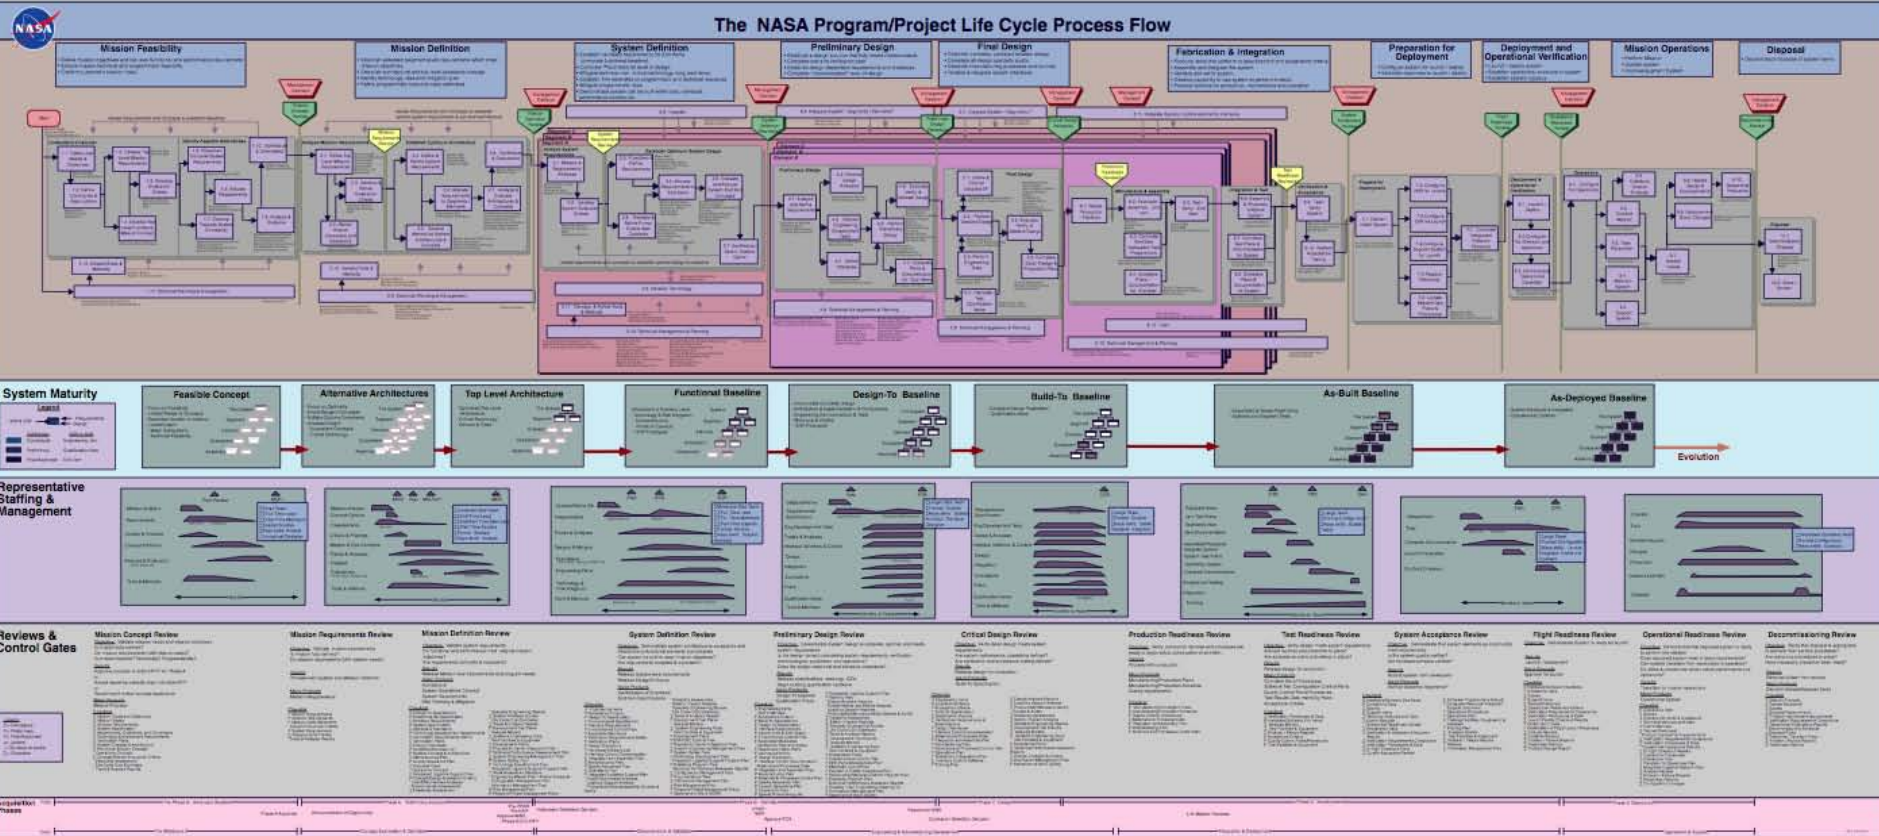

Descartes-Origins

- ▶ Hyperport gives estimates of recurring costs and turnaround times
- ▶ Initial non-recurring activity modeling is needed
- ▶ Same DES approach can be taken to quantify the variability of design, development, testing, and evaluation (DDT&E) and total first unit production (TFU) costs and schedules
- ▶ When completed, Origins can be used with Hyperport to generate full life-cycle estimates for next-generation reusable launch vehicles

Descartes-Origins Objective

- ▶ Documents like this one lay out the various phases, milestones, processes, objectives, and other components of a large NASA acquisition program
- ▶ Similar information was gathered for DoD projects

Researching Program Process Flows

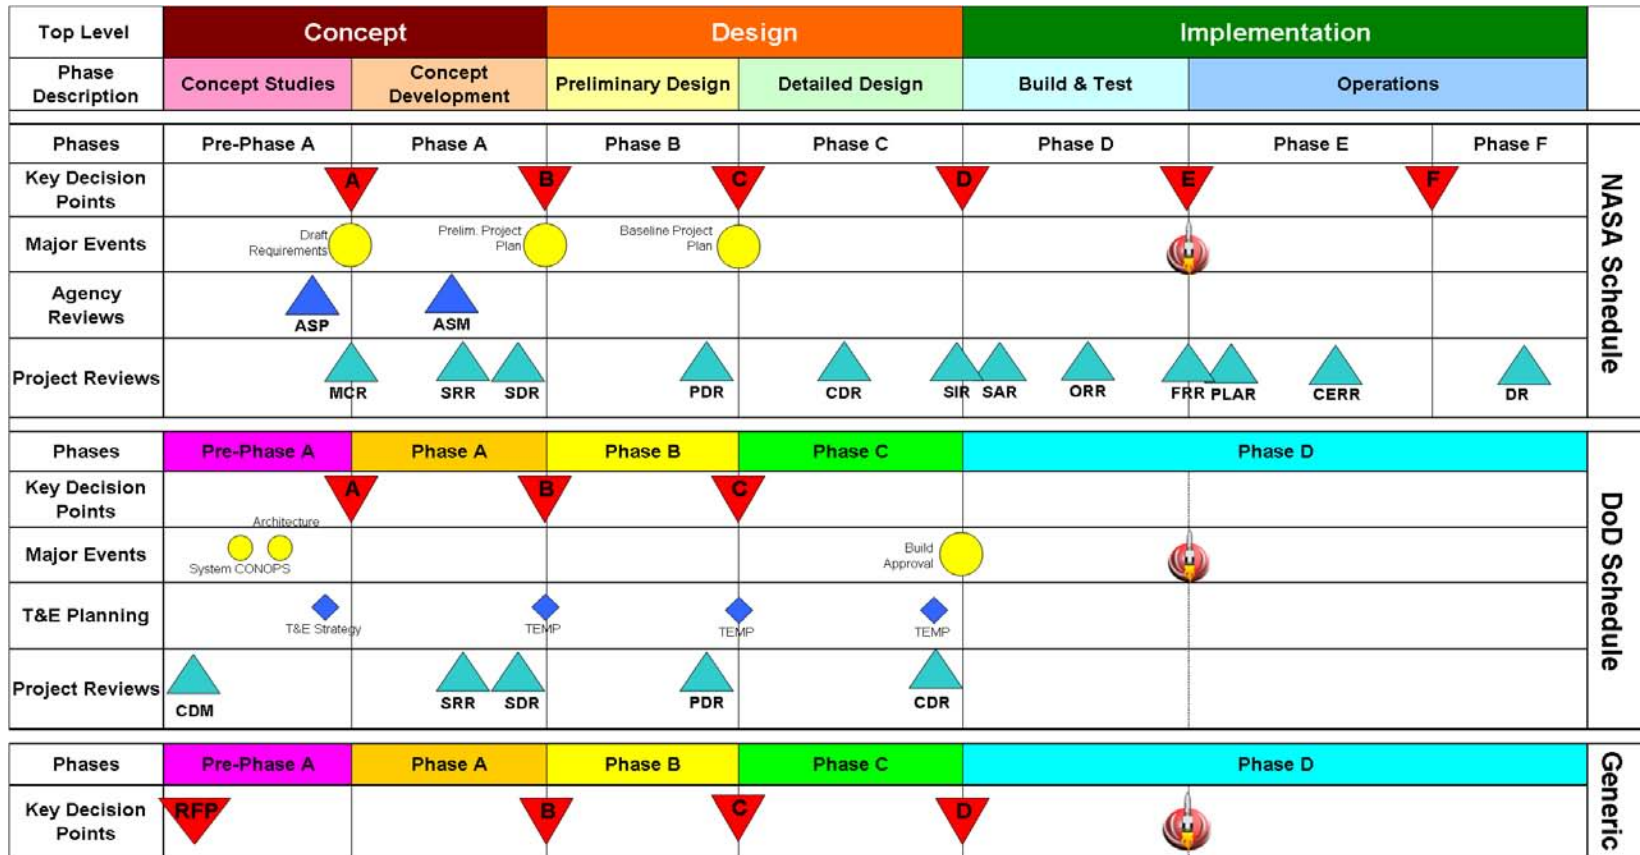

NASA Schedule

DoD Schedule

Generic

- ▶ Summary gathered from multiple sources of NASA and DoD design processes
- ▶ Some terminology differs, but general design phases are similar

Running Origins

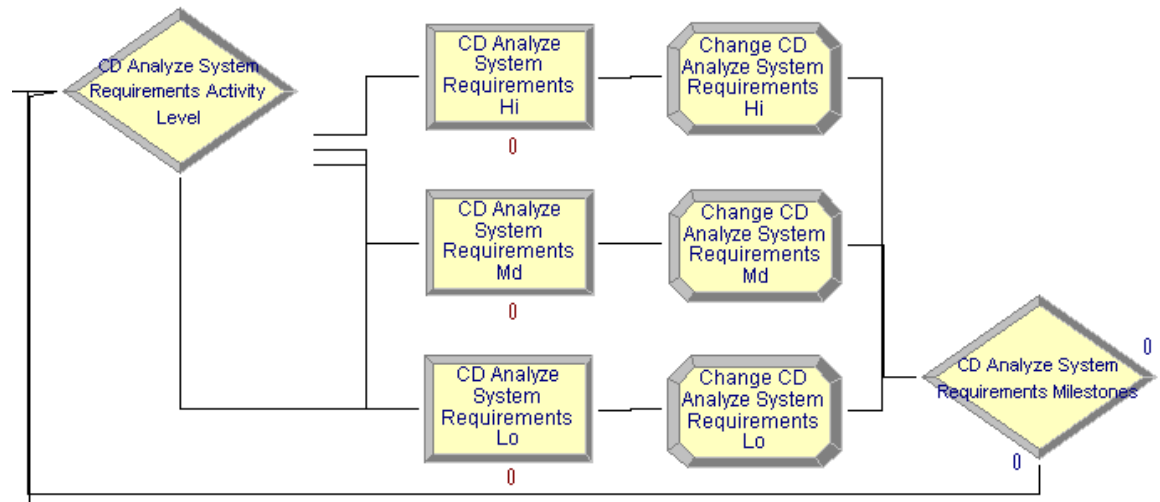

- ▶ Sand chart shows expected costs over time based on averages of numerous trials
- ▶ Separately, the model calculates averages and various measures of spread for:
 - Phase length
 - Phase completion dates
 - Total phase cost in various forms

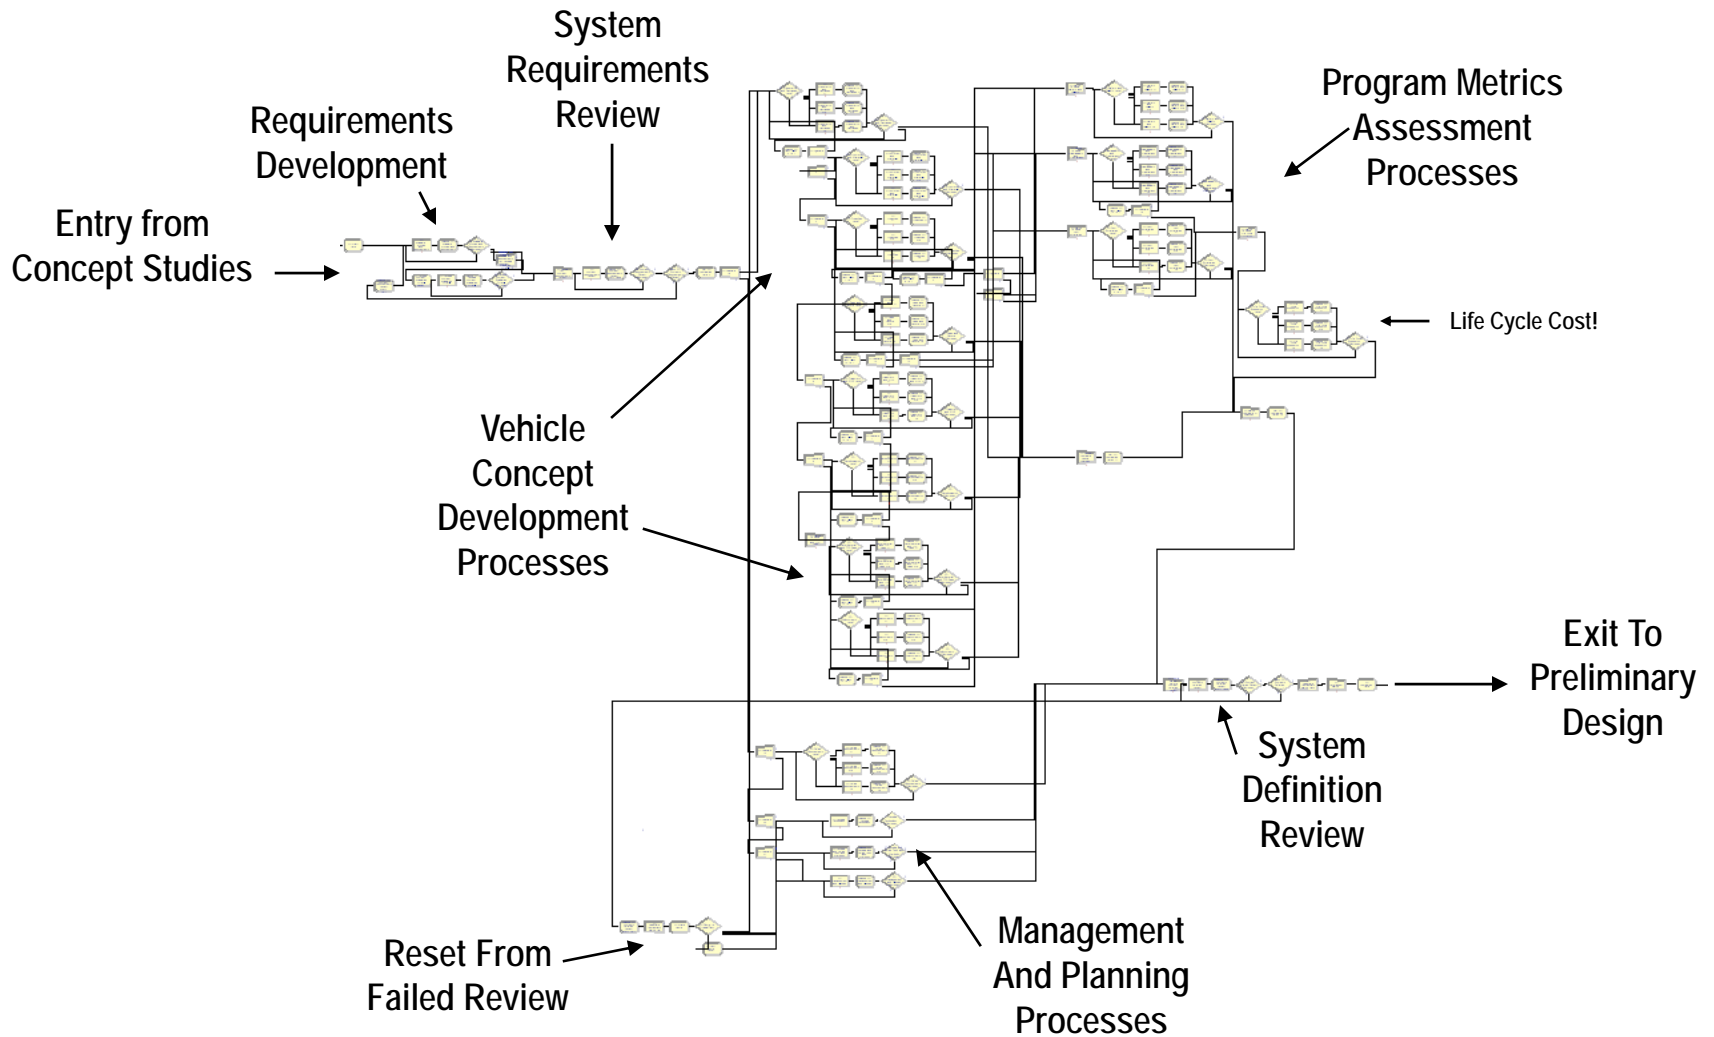

Origins Output Statistics

Model Details

- ▶ Primary ‘tasks’ are modeled using a set of 8 blocks
- ▶ A decide block routes the design entity to a process
- ▶ Process blocks represent different ‘activity levels’
 - Activity levels describe quantity of work done in a single day
 - Each process lasts exactly one day
- ▶ Assign blocks account for work done and update work left
 - Can also randomly generate ‘problems’ that increase work left
- ▶ Depending on work left, final decide can route entity back for another day of work or trigger another task to start

Example: Concept Development (Phase A)

- ▶ Vehicle Concept Development:
 - Geometry and Packaging
 - Structures and Materials
 - Propulsion and Integration
 - Sizing and Closure
 - Trajectory and GNC Simulation
 - Aerodynamics
 - Aerothermal and TPS Sizing
 - Subsystems
- ▶ Program Metrics Assessment:
 - Reliability and Safety
 - Maintainability and Operations
 - Cost Estimation
 - Life Cycle Cost
- ▶ Management and Planning:
 - Technology Development
 - Develop and Refine Tools and Methods
 - Refine Requirements
 - Management and Planning

- ▶ Various processes can interact with each other
 - One may trigger another once it reaches a certain % completion
 - When one finds a 'random problem,' that may propagate to related processes
 - ▶ Ex: if trajectory changes, aerothermal may require some do-over work
 - Failed reviews add time back on to all processes in their area

Budget Controls

If simulating with unlimited budget, this section is ignored.

Units:

Quarters Millions

Periods \$ / Period

User Input Sheet (in progress)

- ▶ Each task has a set of variables and arrays related to it

- ▶ Work Left (2 values)
 - The initial expected work to be done
 - The current quantity of work remaining

- ▶ Task Levels (3 values)
 - Amount of work done per day in high, medium and low-workload situations

- ▶ Activity Efficiency (3 values)
 - If many people are working on a task, the extra communication required lowers the efficiency
 - If a person spends very little time on a task, the work tends to be less productive due to start-up costs

- ▶ **Problem Rate (3 values)**
 - The chance of a day's worth of work uncovering some sort of problem that will require additional time/work to fix
 - Chances are higher on days working at higher activity levels
- ▶ **Tasks Affected, New Work (n values)**
 - A problem found in one task will add work to itself, but may also add work for other tasks
 - Actual quantity of new work is randomly generated but with a mean defined here
- ▶ **Review Success Chance (1 value)**
 - If a review immediately follows a task, the chance of passing the review on the first attempt
 - This value is increased on a second review attempt

Conclusions

- ▶ What aspects of launch vehicle programs make them susceptible to cost overruns and/or schedule slippages?
- ▶ Are there particular phases of a project where minor slippages tend to ‘snowball’?
- ▶ Which phases tend to create the most overall variability?
- ▶ What can be done to reduce both cost and variability of cost for these programs?

...and the Big Question:

- ▶ From a complete Life Cycle standpoint, are RLVs or ELVs cheaper for a given flight rate?

What We Can Learn

Current Status and Validation and Future Work

- ▶ Private companies and government programs are developing next-generation RLVs
- ▶ Design decisions will be made based on vehicle performance, but also on cost, reliability, and long-term maintainability projections
- ▶ SEI's Descartes tools will give programs the Life Cycle estimates they need to help make those decisions
